1. Overview

With the rapid development of data center, the energy consumption problems about the data center have become increasingly serious, and energy management and the design of power supply and distribution have become hot problems; efficient and reliable power distribution system scheme for data center is an effective method to improve the power utilization efficiency of the data center and reduce the energy consumption of equipment. In order to achieve the energy conservation of data center, firstly it is necessary to accurately monitor each electricity load, but there are many loading circuits in the data center, and the traditional measuring instruments are incapable of satisfying the requirements for cost, volume, installation, construction and the like; hence, it is necessary to apply multi-circuit monitoring device applicable to the centralized monitoring requirements of datacenter.

AMC16 series multi-circuit monitoring device of Acrel Company is a measuring device designed specifically for the power supply management of server in the data center. Such device is small and exquisite in design, capable of centralized monitoring on various electric parameters and on-off states of dozens of circuits, including incoming line circuit and outgoing line circuit, and it achieves the highly integration of monitoring circuits in volume.

2. Type description

Туре	Functional description	Optional functions			
AMC16MA	Busbar voltage for measurement of three-phase total incoming lines + 2-way three-phase incoming line current, active power, reactive power, power factor, active energy, reactive energy + 36-way single- phase outgoing line (12-way three-phase) current, active power, reactive power, power factor, active energy, reactive energy +1-way on-off output +1-way RS485 communication.	2C-duplex communication			
AMC16MA H	Increase 2-15 sub-frequency harmonic and total harmonic of incoming line voltage,incoming line current and outgoing line current based on the function of AMC16MA	Dual-power supply may be required			
AMC16MD	C16MD Outgoing line for measurement of DC busbar voltage +42-way direct current,active energy+1-way on-off output +1-way RS485 communication				
AMC16Z	Busbar voltage for measurement of three-phase total incoming lines + 1-way three-phase incoming line current, active power, reactive power, power factor, active energy, reactive energy + 21-way single- phase outgoing line (7-way three-phase) current, active power, reactive power, power factor, active energy, reactive energy + 1-way on-off output +1-way RS485 communication+21-way active on-off input (AC220V) + 1-way reactive on-off input				
AMC16ZH	Increase 2-15 sub-frequency harmonic and total harmonic of incoming line voltage,incoming line current and outgoing line current based on the function of AMC16Z				
AMC16ZH- U	Open measurement of outgoing line circuit voltage based on the function of AMC16ZH.				
AMC16K	38-way active on-off input (AC220V) + 4-way reactive on-off input + 1-way on-off output + 1-way RS485 communication

6. Parameter setting

The communication addresses, baud rates and such parameters of all types are set by the dial switch and their setting methods are given in the device panel.

Energy zero clearing: in case of energy metering function and the requirement for energy zero clearing, set the bit of 5-8 (AMC16MA and AMC16MD)/4-1 (AMC16Z) of dial switch to Position-1011 and then re-electrify the device. Upon energy zero clearing, have to set the dial switch to Position-0; in case the dial switch is not reset upon zero clearing, conduct zero clearing operation for each time of electrification.

For the incoming line parts of AMC16MA and AMC16Z, the energy read is primary energy due to secondary current input, and thus it is necessary to firstly set CT transformation ratio through communication, or it is impossible to read the energy of the incoming line.

Note: ON-state of the dial switch is 0-state.

7. Application scheme

Working power supply is from independent DC24V power module

Description:

1. This resistance is applicable to power distribution cabinet of two-way connection with ATS switching device.

One AMC16MA device may be exchanged for 2-way incoming line and 35-way outgoing line, and repeatedly output as per ABC phases. Each outgoing line circuit phase can be configured.
One AMC16K device is capable of monitoring the status of 38 outgoing line switches, and it is directly from the cut-off export, corresponding to the outgoing line of CT module.

4. The working power supply of IMI requires external DC24V switch power supply.

Incoming line

Incoming-line current input

Voltage input

Feed-out state detection

Feed-out 1

Relay output

Outgoing line circuit current output

Reactive on-off status

485 bus to IMI

Working power supply is from independent DC24V power module

Description:

1. This resistance is applicable to power distribution cabinet of one-way incoming line.

2. One AMC16Z device may be exchanged for 1-way incoming line and 21-way outgoing line, and repeatedly output as per ABC phases. Each outgoing line circuit phase can be configured.

3. One AMC16Z device is capable of monitoring the status of 21 outgoing line switches, and

it is directly from the cut-off export, corresponding to the outgoing line of CT module.

4. The working power supply of IMI requires external DC24V switch power supply.

AMC16MD multi-circuit monitoring device DC system application wiring				
DO output				
Communication 2				
Communication 1				
Power supply 2				
Power supply 1				
External switch power supply				

Attentions to wiring:

1. The frequency of AMC16MA and AMC16Z is calculated based on V1 voltage, and therefore V1 voltage access must be ensured, or it may result in inaccurate measurement;

2.It is suggested that 11,12 and 13 should be accessed to voltage (voltage access for three-phase type A,B and C and inparallel voltage access for single-phase type),regardless of single-phase or three-phase AMC16MA and AMC16Z; 3.The current access of outgoing line for AMC16MA and AMC16Z is Phase-A for I1,Phase-B for I2 and Phase-C for I3 by default and so forth;three-phase load shall be accessed based on the order of A,B and C,and phase connected to it needs to be focused for single-phase load circuit,and the phase setting of single-phase circuit should also be conducted based on Method 4 in Note 7.4;or the power,energy and such parameters of the single-phase circuit will be inaccurately measured.

8. Communication protocol

The protocol specifies the physical connection and communication protocol of data exchange by AMC 16 series multicircuit monitoring device and data terminal equipment, and its protocol mode is similar to Modbus_RTU communication protocol.

8.1 Protocol introduction

The communication protocol used for AMC16 series device specifies the data series definition of address code, function code and the check code which are necessary contents for specific data exchange. Such protocol applies master-slave response connection on one communication line (half-duplex), which means that the signal on signal communication lines is transmitted along two opposite directions. Firstly, the signal of the master computer addresses to one sole terminal equipment (slave), and then the response signal sent by the terminal equipment is transmitted to the master in opposite direction.

The protocol only allows the communication between the master (PC,PLC and the like) and the terminal equipment,but not the data exchange between independent terminal equipment;for this purpose,terminal equipment will not occupy the communication line when it is initialized,but only limited to make s response to the consulting signal arriving at the local computer.

8.2 Transmission mode

The information transmission is in asynchronous mode, expressed in byte; and the communication information transmitted between the master and the slave is 11-bite format, including 1 start bit, 8 data bits (minimum significance bit is sent first), odd-even check bit (no check) and 2 stop bits.

8.2.1 Data frame format

Address	Function	Data	CRC check code
code	code	area	
1 byte	1 byte	n bytes	2 bytes

8.2.2 Address field

The address field is at the beginning part of the frame, consisting of one byte (8 binary codes) with decimalism of 0-255; in our system, only 1-247 are used and other addresses are retained. These bits show the addresses of terminal equipment designated by users, and such equipment will receive the data from master connected with it. The address of each set of terminal equipment is sole, and only the terminal addressed will respond to consulting including such address. When the terminal sends back a response, the slave address data in the response will tell the master the terminal which it is communicated with.

8.2.3 Function field

The function field code tells the function which the addressed terminal executes. The function codes and their significance

and functions used for such series of device are listed in the following table.

Code	Significance	Behavior
03	Read data register	Obtain current binary value of one or more registers
16	Preset multiple registers	Set binary values into a series of multiple registers

8.2.4 Data field

The data field includes data necessary for terminal to execute specific function or the data collected by the terminal responding to consulting. Those data contents may be numerical value, reference address or set value. For instance: function field code tells the terminal to read a register and the data field needs to indicate which register is used at the beginning and how many data are read; the embedded address and data vary with the different types and master-slave contents.

8.2.5 Error check field

This field allows the error during the inspection and transmission between master and terminal. Sometimes, due to electrical noise and other disturbance, a set of data may change to some extent on the line when it is transmitted from one set of equipment to another, and the error check is capable of ensuring the master or the terminal not to respond to the data changed during transmission, which improves the system safety and efficiency, and 16-bit cyclic redundancy method is used for the error check (CRC16).

8.2.6 Method for error detection

Error check field occupies two bytes, including one 16-bit binary value. CRC value is calculated by transmission equipment and then added to the data frame; the receiving equipment re-calculates CRC value when receiving data and then compares the value in CRC field received; if two values are not the same, error appears.

In CRC operation, firstly preset one 16-bit register as full-1, and then continuously operate 8 bits in each byte of data from and current value of such register, generate CRC from 8 data bits of each byte, and avoid the start bit, stop bit and odd-even bit possibly used affecting CRC. When CRC is generated, conduct xor for b bits in each byte and contents in the register, and then shift the results to lower bit, supplement with "0" for higher bit and shift out the least-significant bit (LSB) and detect; if it is 1, conduct a xor operation with such register and one preset fixed value (0A001H); if the least-significant bit is 0, do not make any treatment.

Repeat said treatment till 8 times of shift operation is finished; when the last bit (eighth bit) is shifted, conduct xor operation for next 8-bit byte and current value of the register; similarly, conduct t xor operation for said another 8-times of shift; when all bytes in the data frame have been treated, the final value generated is CRC value.

Process to generate one CRC includes:

(1)Preset one 16-bit register as 0FFFFH (full-1) which is called CRC register.

Conduct xor operation for 8 bits in the first byte of data frame and the lower byte in CRC register and save the result in CRC register.

Shift one bit of CRC register to the right, fill with 0 at the most significant bit, and then shift out and detect the least significant bit.

If the least significant bit is 0: repeat step 3 (next shift); if the least significant bit is 1: conduct xor operation for CRC register and one preset fixed value (0A001H).

Repeat step 3 and step 4 till the eighth times of shift. Thus, a complete eight bits are treated completely.

(2) Repeat step 2 to step 5 to treat the next 8 bits till all bytes are treated completely.

The final value of CRC register is CRC value.

In addition, there is also one method by utilizing preset table to calculate CRC, which is mainly characterized by fast

calculation speed; but the table needs larger storage space, and such method is not detailed herein; please refer to related data.

8.3 Introduction to function code

8.3.1 Function Code 02H: reading discrete magnitude input

This function code reads 1-2000 continuous status of discrete magnitude input. Request PDU specifies the start address, namely the first input address and input number designated. The input is addressed from zero. Thus, the addressing input of 1-16 is 0-15. Based on each bit in the data field, the discrete magnitude input in the response message is divided into one input. The indicating status is 1=ON and 0=OFF. LSB (least significant bit) of the first data byte includes input of address in inquiry. Other inputs are analogized in order till it reaches the high-order end of this byte, and the subsequent bytes are in the order from lower bit to higher one. If the returned input quantity is the multiple of eight, zero will be used to fill the rest bit in the final data byte (till the high-order end of the byte). The byte quantity field shows the complete byte quantity of the data.

The following example shows 10 continuous on-off statuses of DI7-DI16 read by No. 01 Slave.

Master sending		Sending information
Address code		01H
Function code		02H
G 11	Higher byte	00H
Start address	Lower byte	06H
	Higher byte	00H
Output quantity	Lower byte	0AH
CRC check code	Lower byte	18H
	Higher byte	0CH

Slave returning		Returning information
Address code		01H
Function code		02H
Number of bytes		02H
Input status 14-7		3FH
Input status 16-15		02H
CRC Check code	Lower byte	29Н
	Higher byte	89H

Express the discrete magnitude input status of 14-7 as value of 3F with hexadecimal byte or 0011 1111 of binary system. Input 14 is MSB of this byte and Input 7 is LSB of this byte.

Express the discrete magnitude input status of 16-15 as value of 02 with hexadecimal byte or 0000 0010 of binary system. Input 15 is LSB of this byte zero is used to fill in the rest bit in the final data byte.

8.3.2 Function Code 03H: reading register

This function enables users to obtain the data and system parameters collected and recorded by the equipment. The number of data for the primary request of the master is unlimited, but within the address range defined.

The following example shows the basic data collected by No. 1 Salve reading 3 registers (each address in the data frame occupies 2 bytes), including Uab, Ubc and Uca, of which the address of Uab, Ubc and Uca is respectively 03H,04H and 05H.

Master sending		Sending information
Address code		01H
Function code		03H
Start address	Higher byte	00H
	Lower byte	03H

Number of	Higher byte	00H
registers	Lower byte	03H
CRC	Lower byte	F5H
check code	Higher byte	СВН

Slave returning		Returning information
Address	scode	01H
Function	n code	03H
Number of bytes		06H
	Higher byte	0EH
Register data	Lower byte	EEH
	Higher byte	0EH
Register data	Lower byte	E8H
Desister late	Higher byte	0EH
Register data	Lower byte	E9H
CRC check code	Lower byte	8FH
	Higher byte	7EH

8.3.3 Function Code 06H: Writing single register

Function Code 06H allows users to change the content of single register, and the system parameters and on-off output status of this instrument may be read in by this function code.

The following example shows the instrument with preset address of 01 and output on-off DO. The on-off output status indicates the register address is 0045H and corresponding DO closing data is 0x01.

Master sen	Sending	
	information	
Address code	01H	
Function code	06H	
Start address	Higher byte	00H
2	Lower byte	45H
Data to be read in by	Higher byte	00H
0045H	Lower byte	01H
CPC abaak aada	Lower byte	59H
	Higher byte	DFH

Slave returnin	Returning information	
Address code	01H	
Function cod	06H	
Start address	Higher byte	00H
Start address	Lower byte	45H
Read-in data	Higher byte	00H
iteau-in tata	Lower byte	01H
	Lower byte	59H
CRC check code	Higher byte	DFH

8.3.4 Function Code 10H: writing multiple registers

Function Code 10H allows users to change the content of multiple registers, and the system parameters and on-off output status of this instrument may be read in by this function code. The master can write 16 (32-byte) pieces of data once at most.

The following example shows the instrument with preset address of 01 and output on-off DO. The on-off output status indicates the register address is 0045H and the first byte is corresponding to DO.

Master sending		Sending information
Address	code	01H
Function code		10H
	Higher byte	00H
Start address	Lower byte	45H
Number of	Higher byte	00H
registers	Lower byte	01H
Number of b	ytes	02H
Data to be read in by	Higher byte	00H
0045H	Lower byte	01H
	Lower byte	69H
CRC check code	Higher byte	05H

Slave returning		Returning information
Address code		01H
Function code		10H
G 11	Higher byte	00H
Start address	Lower byte	45H
Number of	Higher byte	00H
registers	Lower byte	01H
	Lower byte	10H
CRC check code	Higher byte	1CH

8.4 Table of communication addresses

Ad	ldress	Parameter	Numerical range	Read- write	Data type

Notes: 1. Said address table is applicable to all devices. The harmonic data are applicable to H-type.

2. Electric energy communication data are primary-side data, expressed in 0.01kWh.

For example: address value of read 0x0DH and read and 0x0EH is respectively 0x1234H and 0x5678H and actual primary-side energy value is 0x12345678H (3054198.96kWh).

3. The register address in said address table is expressed by hexadecimal value.

4.The circuit phase of outgoing line needs being set based on actual phase connected to the current, with correspondence A,B and C to 1,2 and 3, which will be default parameters in case of exceeding the range. For example: the current of outgoing line 1 and outgoing line 2 is Phase-A load and Phase-B load respectively; then 0x190H address parameter should be set as 0x0201H, or it is impossible to accurately measure the power and energy of outgoing line 1 outgoing line 2 circuits.

5.In practical use, users need to read corresponding address parameters based on the type of device actually used. When users are reading certain register parameter, they should pay attention to the number of bytes and high-low bit of address when the parameter occupies and the expression method of such value (some values when reading need binary representation, some need decimalism representation and some data are signed numbers).

6.Due to external Hall sensor used for AMC16MD, the null points of different hall sensors may be different; thus, in practical use, upon the wiring of Hall sensor and AMC16MD and power-on of Hall sensor and before the load not input, it is necessary to adjust the null point of AMC16MD (0x1A4H-0x1CDH) till the null points of way 1-42 DC currents become zero.

7.AMC16MD is only allowed for 50mA current signal as the input signal, and the primary-side current value can be set by writing order through communication based on the actual condition.

9.Attentions

9.1 Before device communication, it is necessary to set the value of dial switch to make the communication address and Baud rate of the device satisfactory.

9.2 The device shall be installed in dry and clean place far away from the heat and strong electromagnetic field.

9.3 In device wiring, attention shall be paid the phase sequence and the polarity of the AC voltage and current, or it will lead to inaccurate measurement.

9.4 CT shall be used for current input and the CT transformation ratio of incoming line requires being set through communication.

9.5 CT accuracy has an impact on the measurement accuracy of the device. The angular difference of CT will have an impact on the measurement accuracy of the power of energy of the device.

9.6 It shall be provided with 2A fuse when it is applied to direct access system with PT.

9.7 CT grounding terminals of current input on the device should be separately led to the grounding terminals, and it is not allowed to firstly connect the grounding terminal of the current input in parallel on the device and then lead to the grounding terminal.

9.8 Communication cable should be shielded twisted pair.

9.9 Each current phase of outgoing line circuit needs being adjusted as per actual access, and the adjustment method is by reference to Note 4 in 7.4.

10.Common faults and reason analysis

10.1 Inaccurate measurement of device

*Check the correctness of voltage and current wiring and the correctness of incoming and outgoing line of current input;

*Check whether CT setting of device is corresponding to CT actually used externally;

10.2 Correct voltage and current measurement but inaccurate power measurement

*Check the correctness of current input direction;

*Check the correctness of phase corresponding to each current circuit;adjust the outgoing line circuit based on the actual access;

10.3 Abnormal communication

*Check the normal connection of communication connecting line;

*Check the interlacing of Terminal A and Terminal B of communication;

*Check the correctness of device address setting and the correctness of setting of communication Baud rate;

* In case of abnormal communication of multiple devices, firstly test the abnormality of single-machine communication;

10.4 Incoming line voltage, current and power are available, but the energy is without numerical value

*Check CT transformation ratio setting of incoming line

10.5 There is numerical value in AMC16MD when the load is free of current

*Adjust the null-point value of current of AMC16MD. (Null point of DC Hall sensor is greatly different from it and needs adjustment)
